

User-friendly software for survival modelling with GUTS

Abstract for poster

Session: Effect modelling for regulatory risk assessment: current applications and future directions

Track: 4. Ecological risk assessment and human health risk assessment of chemicals, mixtures and stressors and risk mitigation strategies

Tjalling Jager, Magnus Wang and Roman Ashauer

Mechanistic effect models are rapidly gaining interest in the context of environmental risk assessment. In 2018, this interest culminated in a dedicated EFSA opinion on toxicokinetic-toxicodynamic (TKTD) models for use in aquatic risk assessment of pesticides. This opinion focussed on three modelling frameworks; for the endpoint survival, the focus was on GUTS (the General Unified Threshold model for Survival). Since the EFSA opinion judged GUTS to be “ready to be used in risk assessment”, there is now a pressing need for robust and user-friendly software to perform analyses with this model, following the proposed workflow in the opinion. In a Cefic-LRI funded project, we are currently developing such a software. The resulting software will be able to perform the procedures for calibration, testing and model predictions as outlined in the EFSA opinion. Furthermore, it will perform these analyses with minimal demands on user experience in modelling and statistics. However, this software will not be restricted to risk assessment of pesticides. It can also be used for other tasks, such as the derivation of classical LC50 values (as function of time) from standard and non-standard toxicity data, using all of the observation on survival over time. Specifically, the software will enable meaningful calibration to toxicity data that result from tests with time-varying exposure, which cannot be achieved using traditional dose-response curves. The software is planned to be released by the end of 2019, but in this contribution, we provide a sneak preview of the software’s layout, algorithm, functionality and look.
